

## Supplement 2. Chemical composition of the Hanzhong bronzes

**Analytical method:** Compositional analyses were carried out by Electron Probe Microanalysis (EPMA) with Wavelength Dispersive Spectrometer (EPMA-WDS), using a JEOL 8100 Superprobe in the Wolfson Archaeological Science Laboratory at the UCL Institute of Archaeology. Operating conditions were an accelerating voltage of 20 kV and an absorbed electron current of approximately  $5 \times 10^{-8}$  A. Detection limits for most elements were around 100 to 200 ppm but could be as high as 400 ppm for arsenic. The measured intensities were quantified against pure or binary compounds using JEOL's ZAF correction procedure. Seven to nine micro-areas, each about 0.015 square millimetres, were analyzed in each sample and the mean value of these micro-areas was calculated and used as quantitative result for that sample, in order to reduce the error caused by potential heterogeneity of samples.

**Note for the table:** “—” means below detection limit; “tr.” means trace, i.e. visible peak but below confidence level.
