

Estimating the timescale of *Lobaria* diversification

The Lichenologist

Cornejo & Scheidegger

Swiss Federal Research Institute WSL

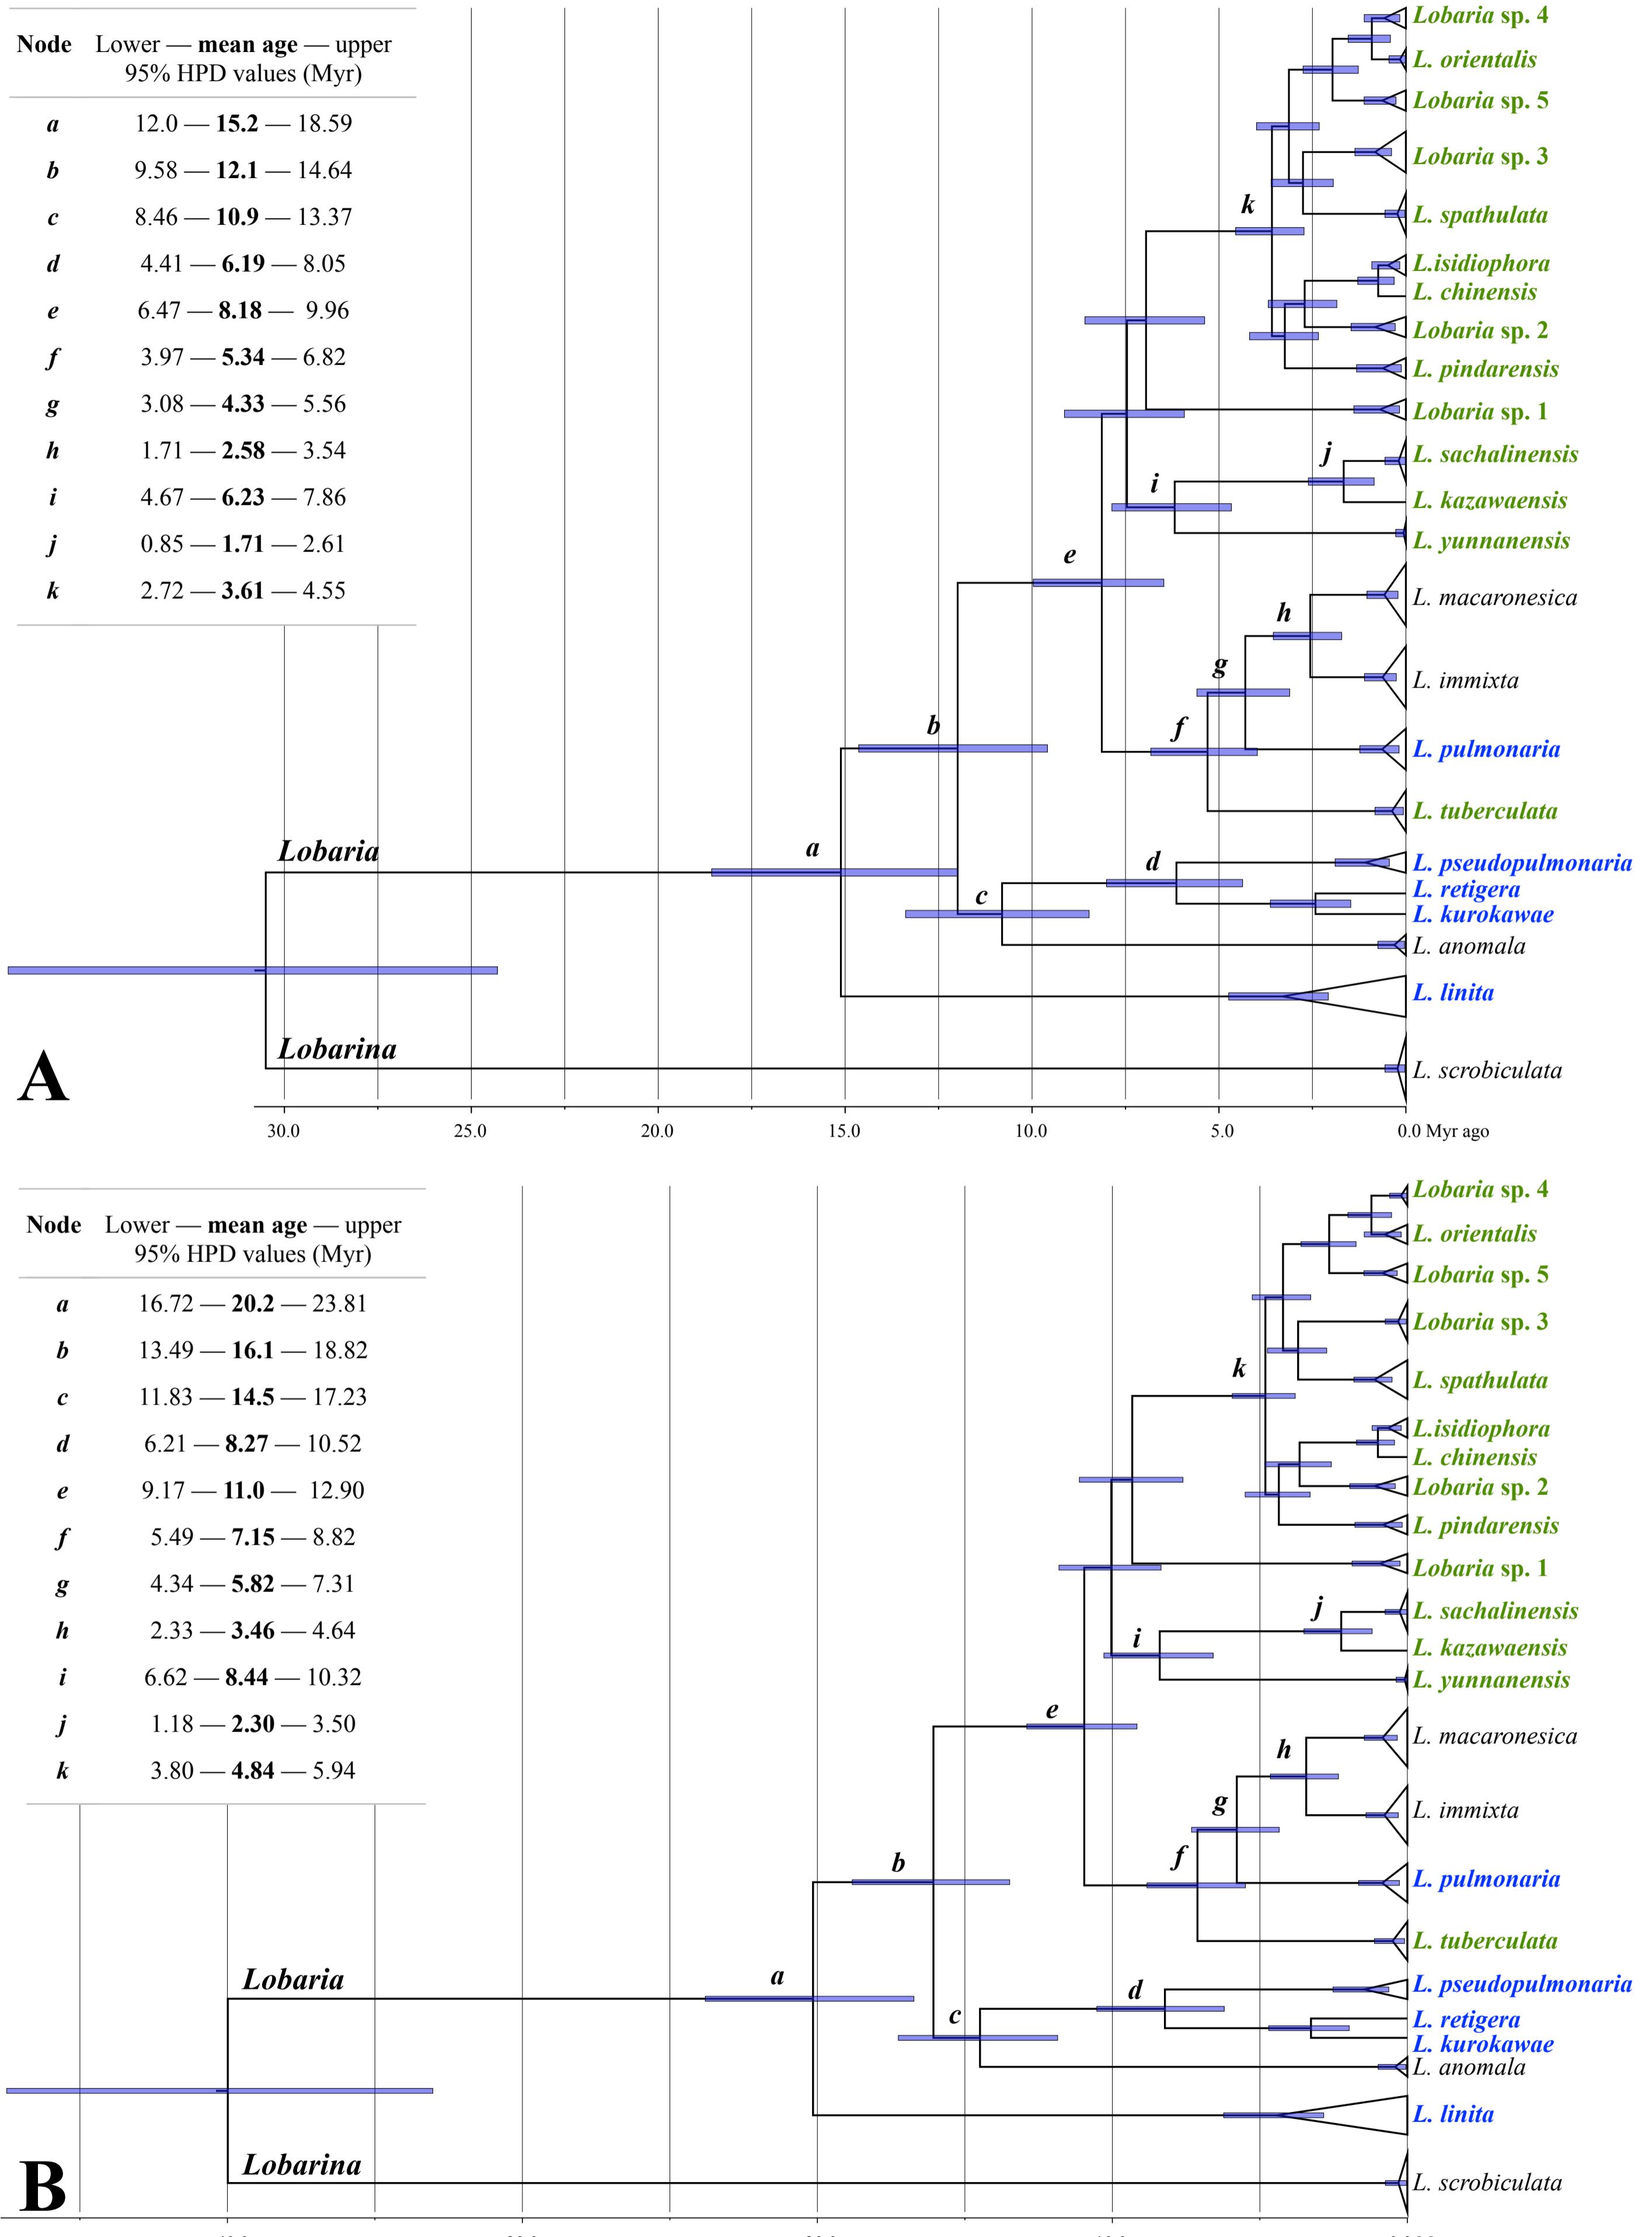

Figure S1. Timetrees of the genus *Lobaria* obtained from Bayesian analysis (BEAST 1.84). Analysis **A** used an RPB2 mutation rate as calibration reference (= 1.50 substitutions/site/year $\times 10^{-9}$; Leavitt *et al.* 2012). Analysis **B** used two mutation rates as calibration references (RPB2, and nrITS = 2.40 substitutions/site/year $\times 10^{-9}$; Leavitt *et al.* 2012). Most branches obtained posterior probability values of at least 0.98. The mean ages for *a*–*k* are given in the table at the top left for each analysis. Species written in bold green are exclusively from East Asia, and those in bold blue also grow in North America and other regions. Only *L. anomala* (West Pacific coast), *L. immixta* and *L. macaronesica* (both Macaronesian Islands in the North Atlantic) grow outside of East Asia.
