26 **Appendix S2. Linearity of the relationship between individuals' oxygen uptake and incubation time**

27 Metabolic rates ( $MO_2$ ) were quantified in our study by measuring the oxygen ( $O_2$ ) uptake taken at two single  
28 moments along the incubation period. The reliability of this approach was assessed by testing the linearity of the  
29 relationship between  $O_2$  uptake and incubation time (Marginal  $R^2$  / Conditional  $R^2 = 0.91 / 0.96$ ,  $df = 1$ ,  $P <$   
30  $0.001$ , Fig. S1) for a subset of 18 specimens of *Ophryotrocha labronica* not used for the experiment.  
31 Specifically, individual  $O_2$  uptake was measured at 24 °C every 30 min for approx. 3.5 h (between 100 and 50 %  
32 air saturation) and quantified as the difference between the  $O_2$  concentration measured at the beginning of the  
33 trial and that measured at a specific time along the incubation. Values were corrected for the background  
34 respiration by subtracting the mean  $O_2$  uptake measured at each round in six “blank” vials. The relationship  
35 between individual  $O_2$  uptake and time was examined using a linear mixed model that included individual  
36 identity as random effect. Residuals were normally distributed (Shapiro test,  $P > 0.05$ ) and homogeneity of  
37 variance was indicated by a random pattern in the residuals *versus* fitted plot.

38

39

40 **Fig. S1.** Relationship between O<sub>2</sub> uptake and incubation time in individuals of *Ophryotrocha labronica* exposed  
41 to 24 °C (n = 18). Solid, black circles represent [O<sub>2</sub>] measurements performed in a single vial, the black  
42 continuous line represents the regression line, and 95 % CI are indicated by the grey area.

44

### 45 **Appendix S3. Validation of the metabolic rate measurements**

46 Validation of the data on metabolic rates ( $MO_2$ ) of *Ophryotrocha labronica* was achieved by comparing our  
47 measurements, obtained at 24 °C on 18 specimens used for assessing the linearity of the relationship between  
48 oxygen concentration and incubation time (see for details Appendix S2), with those found in the literature from  
49 other marine annelid species from temperate regions. Only species exposed to 24 or 25 °C were selected for  
50 further analyses: *Alitta succinea* (mass 187.5 mg, Sturdivant et al. 2015), *Amphiglena mediterranea* (mass 0.483  
51 mg, Calosi et al. 2013a), *Lysidice collaris* (mass 10.9 mg, Calosi et al. 2013a), *Lysidice ninetta* (mass 7.8 mg,  
52 Calosi et al. 2013a), *Neanthes japonica* (mass 620.0 – 2340.0 mg, (Liu et al. 2009)), *Platynereis dumerilii* (mass  
53 21.3 mg, Calosi et al. 2013a), and *Polyophtalmus pictus* (mass 7.2 mg, Calosi et al. 2013a). The relationship  
54 between  $MO_2$  and wet body mass was assessed using a linear regression model and its 95 % CI, initially  
55 excluding our data. The intercept of the relationship was forced to 0, as no oxygen is consumed in the absence of  
56 biomass. We considered our data validated if it was included within the 95% CI around the regression curve.  
57 According to our results,  $MO_2$  increased with wet body mass across species, following a linear trend ( $R^2 = 0.99$ ,  
58  $F_{1,8} = 766$ ,  $p < 0.001$ ), and the predicted  $MO_2$  value for an annelid species averaging the size of *O. labronica* ( $0.5$   
59  $\pm 0.05$  mg [mean  $\pm$  SE], Carignan, Beaudet and Debacker unpublished data) was predicted to be  $0.008 \mu\text{mol O}_2$   
60  $\text{h}^{-1}$  (CI = [0.007, 0.009]). The mean  $MO_2$  value measured for *O. labronica* at 24 °C,  $0.009 \mu\text{mol O}_2 \text{h}^{-1}$ , laid  
61 within this interval of confidence, thus validating the reliability of our measurements (Fig. S2).

62

63 **Fig. S2.** Relationship between metabolic rates ( $\text{MO}_2$ ) and wet body mass in temperate marine annelids exposed  
 64 to 24–25 °C. The continuous black line represents the linear regression curve, the area delimited by the dashed  
 65 lines its 95% CI, and the red triangle the mean  $\text{MO}_2$  experimentally measured at 24 °C in our study for a subset  
 66 of individuals of *Ophryotrocha labronica* (n = 18).
